## INTRODUCTION

Sample costs to establish a Christmas tree plantation and produce Christmas trees in the Sierra Nevada Foothills - El Dorado, Nevada and Placer Counties are presented in this study. This study is intended as a guide only, and can be used to make production decisions, determine potential returns, prepare budgets and evaluate production loans. The production practices described in this study are those considered typical for growing Christmas trees in the region, but they will not apply to every situation. Sample costs for labor, materials, equipment, and custom services are based on current figures. A blank column, "Your Costs", in Tables 1 and 5 is provided to enter your farm costs.

The hypothetical farm operation, production practices, overhead, and calculations are described under the assumptions. For additional information or an explanation of the calculations used in the study, call the Department of Agricultural and Resource Economics, University of California, Davis, (530) 752-3589 or your local UC Cooperative Extension office.

Sample Cost of Production Studies for many commodities can be downloaded at http://coststudies.ucdavis.edu, requested through the Department of Agricultural and Resource Economics, UC Davis, (530) 752-4424 or obtained from the local county UC Cooperative Extension offices. Some archived studies are also available on the website.

## ASSUMPTIONS

The assumptions refer to Tables 1 to 11 and pertain to sample costs to produce Christmas trees in the Sierra Nevada Foothills - El Dorado, Placer and Nevada Counties. The cultural practices described and materials used are considered typical for a well-managed plantation in the regions. The costs, materials, and practices will not apply to all situations. Establishment and production practices vary by grower and the differences can be significant. The study does not represent a single plantation and is to be used as a guide only. The use of trade names and cultural practices in this report does not constitute an endorsement or recommendation by the University of California nor is any criticism implied by omission of other similar products or cultural practices.

Land. The hypothetical farm, located on land with a $15 \%$ slope, is owned and operated by the grower. The contiguous 20 -acre farm consist of a choose and cut tree plantation of which 16 acres are planted to Christmas trees. One-half of the 16 acres is planted to Douglas fir and one-half to white fir. Field roads, parking areas, and sales areas occupy two acres. The remaining two acres are homestead and unplantable acres. The farm elevation is assumed to be between 1,500 and 4,000-foot elevation.

Production Operating Costs<br>for<br>Douglas Fir, Tables 1 - 4<br>White Fir, Tables 5-8<br>Whole Farm Tables 9-11

General Operations. Typically, a grower establishing a Christmas tree plantation (farm) will plant a portion of the acreage over a period of years until the farm is in full production. In this study, the Even-Age System is used. In this system the cultural practices and trees are the same species for the entire block and the cull trees are eliminated at final harvest. The trees in the block are the same age and once the block is cut, it is replanted. The Uneven-Age System provides continuous trees. The grower may plant several blocks or the entire farm. As the trees are harvested they are replanted with seedlings or stump culture is used to start a new tree, resulting in different age and size trees in the block. Stump culture is the practice of leaving a few lower branches on the stump to serve as "nurse branches" until a shoot sprouts to produce a new tree. In this study, it is assumed the grower will plant one acre of Douglas fir and one acre of white fir each year, but for the overall farm calculations it is assumed that the entire 16 acres are planted. Growers use many other layouts and methods of establishing new trees and will incur similar costs.

Site Preparation. Costs for clearing the land are highly variable and therefore are not included in the establishment cost. The costs will depend on if the land was farmed previously, the amount of brush, tree stumps and rocks that need to be cleared. In August or September in the year prior to planting, the planting block is marked (5-hours/acre), soil samples for nutrient analysis are taken and then the land is ripped in two directions. A custom operator does the ripping when the soil is dry to get a good shatter or breaking up of the soil. Ripping should be done in the tree rows to make planting (digging) easier and faster. In January, prior to planting, the grower disks, harrows, or rototills the land.

Trees. Several species of trees are available for planting, but Douglas fir (Pseudotsuga menziesii) and White fir (Abies concolora, a "true" fir) are planted on this plantation. The Douglas fir represents species that can be grown on the lower elevations and white fir represents the true firs that can be grown at the higher elevations. Also, the Douglas Firs are ready for sale in $6-8$ years and the White Fir in $8-10$ years. The true firs (Abies $s p$.) also include the Red Fir (Silver Tip) and others (Noble, Nordmann, etc.). Tree species are not genetically pure meaning there is variation among the seedlings. Some trees will grow faster than others within the same planting lot. In addition, variations in soil, moisture and nutrients will affect individual tree growth.

Plant. In February, the tree sites are marked and the trees planted, but tree rows and roads may be laid out prior to ripping. Young tree plugs ( $\mathrm{P}-1$ ) are purchased at $\$ 0.50$ each from a reputable nursery. Two people plant the tree plugs ( $\mathrm{P}-1$ ), one person using a power drill/auger digs the hole and the other person plants the tree (put in hole and fill with dirt). Planting time per tree will depend on planting method and firmness of the soil, and may be as high as 80 man-hours per acre. In this study it takes 20 hours ( 40 man-hours) to plant one acre. The trees for this study are planted on a $5 \times 5$-foot square spacing, 1,742 trees per acre. More trees per acre may be obtained by planting on a triangular pattern. The farm is divided into one-acre blocks approximately 165 feet X 264 feet with 15 -foot roads around each block. Block configuration varies with the slope and shape of the farm. In the second year, due to mortality, $20 \%$ (348) of the trees planted the previous year are replanted. After planting, in a separate pass reusable shadecloth (shingles) that protect the seedling from the direct sun are placed on the south side of each tree. It takes approximate 20 seconds per tree or 9.68 man-hours per acre to set the shingles in place. The shades are removed in October and it takes two men 2.5 hours per acre to pull and place the shades in storage.

Irrigation. Water costs include district water at $\$ 2.76$ per acre-inch. The grower may also pay a basic per farm water charge assessed by the district (shown under Cash Overhead). Water and basic monthly charges vary by district and whether gravity feed or pumped. Labor is calculated at 0.15 hours per acre per irrigation. The field is drip irrigated weekly from June to September. Some farms do not irrigate, especially those in

| Table A. Total |  |  |
| :--- | :---: | :---: |
| Water Applied |  |  |
| Year | Douglas Fir | White Fir |
| acre-inches |  |  |
| $1-2$ | 1 | 1 |
| $3-4$ | 4 | 2 |
| 5 | 10 | 4 |
| $6-7$ | 18 | 10 |
| $8+$ | 18 | 18 | the upper elevations in this region. Also overhead sprinklers are common in the area and application times and labor costs may be different than drip irrigation. Actual crop water use for the area was not available, but from limited data from other regions and grower estimates, water in this study was applied according to the calculations shown in Table A.

Fertilization. Soil samples at 0.33 samples per acre or five samples per 16 acres are taken prior to ripping. Fertilizer should be applied according to the analysis recommendations. In this study, no fertilizer is applied during the first three years to the Douglas fir and the first four years to the white fir. Beginning in late May or early June of the fourth year, nitrogen fertilizer as Urea (46-0-0) at 200 pounds per acre ( 92 pounds of nitrogen) per season is applied to the Douglas fir trees and beginning in the fifth year to the white fir trees. The fertilizer is applied by hand and the grower's tractor and trailer are used to haul the fertilizer to the field. The estimated application time is 40 minutes per acre, which includes loading the bags on the trailer and driving to and from the field ( 10 minutes/acre) plus an application time of 30 minutes per acre.

Pest Management. The growers use the pesticides and rates mentioned in this cost study. For more information on other pesticides available, pest identification, monitoring, and management, contact your UC Cooperative Extension farm advisor. Pesticide costs may vary by location and grower volume. Pesticide costs in this study are taken from a single dealer and shown as full retail.

Weeds. In the first year and second year, after planting and prior to budbreak, Atrazine herbicide is applied over the tops of the trees to the row middles and tree rows using a small tractor and sprayer with 10 -foot boom. Two applications of Roundup to control various weeds that germinated since the last spraying are applied as needed - May and August in this study during the first three years. In the fourth year and subsequent years, Roundup is applied with a backpack sprayer one time in May. Each application is assumed to take onehour per acre. Hand weeding ( 3 hours/acre) around the base of the trees is done in July during the first three years. In the fourth year, mulch provided free by tree pruning companies, is spread by hand ( 12 hours/acre) for weed control, erosion control, walking, and soil moisture retention.

Insects. Aphids, mites, and ants can be a problem in Christmas trees. Typically not all trees are affected and the grower would tend to spray individual trees as needed. For this study, a uniform spray for aphid control (Asana) is applied to the plantation in April using the grower's tractor and boom sprayer in the first two years with one-half rate applied during the first year. Beginning in the third year, the grower parks the pressure sprayer in the roadway, with a long hose attached to the sprayer and with a hose end wand, sprays the individual trees and the application takes one-hour per acre. The application costs include fuel costs for running the pressure sprayer, labor and materials. In the Douglas fir, aphids are controlled with a single application in the spring (April) during the first five years, and in both the spring and late summer/fall (September/October) during the sixth, seventh, and eighth years. White fir is treated in the spring during the first seven years and in the spring and fall during the eighth, ninth, and tenth years. Mites are controlled with Floramite miticide beginning in July of the second year, again using the pressure sprayer and wand. Lower rates of materials may be applied in the early years because of the small trees. Common alternative methods are that the grower will apply the materials with a backpack sprayer or apply with a backpack sprayer and use the pressure sprayer in the field for volume mixing and filling the backpack sprayer. Insecticide applications with the backpack or wand are assumed to take one-hour per application.

Disease. Douglas fir is susceptible to Swiss Needle Cast (Phaeocryptopus gaeumannii) and Rhabdocline Needle Cast fungi ( $R$. pseudosugae \& R. weirii). Bravo Weather Stik fungicide is applied in May beginning in the fourth year using the grower's tractor with the pressure sprayer and wand. Each application takes one-hour to apply. White fir is not susceptible to these needle pathogens, and therefore is not treated.

Vertebrates. Gophers can be a problem and are monitored beginning in the first year. During the first three years, gophers are controlled twice a year (May, September) with gopher bait. In the fourth and subsequent years, gophers are monitored and treated as needed. In this study, gophers are baited one time (May) during the fourth and subsequent years. Each bait application is assumed to take one-hour to walk the field and place the bait.

Prune (Double Leaders/Leader Control). Leader (growing tip) control is done on both the Douglas and white fir. Pruning to remove double leaders begins in the second year. In the fifth and subsequent years, pruning is done to control the leader length (keeping leaders in check). Hand clippers are used for pruning the leaders and the pruning is done anytime during the season.

Table B. Pruning Times in Hours Per Acre

| Douglas Fir |  |  |  |  |  |  |  |  |  |  |  |

| Shape |  |  |  | 5.00 | 5.00 | 5.00 | 5.00 | 5.00 | 0.75 | 25.75 |  |
| Basal |  |  |  | 87.00 |  |  |  |  |  |  | 87.00 |

Typically, the pruning is done each time the grower walks the field and not all trees will require pruning or all be done at the same time, but in this study a time (June) has been selected. Some lengthy side branches may also be clipped at the same time. Pruning times will vary considerably by grower, location, tree species and other factors. The pruning times in this study (Table B) are estimated from grower input and various cost studies.

Shear. Shearing is the shaping of side branches to the desired taper and to make the tree fuller. Shearing is done on Douglas fir beginning in the fourth or fifth year or when the trees are 3.5 to 5.0 feet high and is done each year until the tree is harvested. Shearing times in Douglas fir will vary depending on method (mechanical or hand). Times can range from seven seconds per tree with a mechanical hand shear to 30 seconds or longer per tree with a machete. Most growers in the area do not shear white fir. In this study, five hours per acre is allocated to minor pruning or shaping (clipping a few branch tips) of the white fir trees, beginning in July of the fifth year.

Basal Prune. Branches are removed on what is or will be the basal portion (handle) of the tree; the section on the tree trunk that supports the tree in the tree stand. The branches are removed in October of the fourth year, although it can be done any month except June and July, and may be done in other years, but is only done one time during the tree life. According to grower information, it takes an average of four minutes per tree.

Harvest. In this study, it is assumed that $80 \%$ of the planted trees are sold. At the Choose-N-Cut Christmas tree farms, the customer selects and cuts the tree with a saw provided by the grower. Labor is provided by the grower to collect tree payment, to assist the customer as necessary, to net the tree, and to load the tree on the customer's vehicle. On some tree farms, the customer selects the tree and the grower's labor cuts the trees. The grower usually hires local labor during the weekends beginning with the Thanksgiving weekend. Twelve to 15 individuals are hired to cover the various shifts. The number of individuals per shift will vary by day and time. A minimum staff, such as the grower and one assistant, is on duty during the week. For this study, a full staff is allocated to the harvest during the seventh year for Douglas fir and ninth year for White fir, when $65 \%$ of the trees are sold and this time is the basis for labor costs for the sixth (5\%) and eighth year (10\%) for Douglas fir and the eighth ( $5 \%$ ) and tenth ( $10 \%$ ) for white fir. Most trees are netted prior to loading on the customer vehicle and a charge per tree is included in the harvest materials and labor operation cost.

Yields. Because of the genetic and environmental variability and in addition to customer preference, a few Douglas fir trees are sold in the sixth year (5\%). Most of the trees are sold in the seventh year ( $65 \%$ ) and the remaining saleable trees are sold in the eighth year (10\%). It is assumed that $20 \%$ of the trees will have died or not meet customer expectations and will not be sold. These trees are destroyed prior to the next planting. White fir trees are sold in same ratio as the Douglas fir beginning in the eighth year.

Returns. In this study, it is assumed that the farm is located in a high traffic area and that $80 \%$ of the planted trees are sold. The trees are sold for $\$ 34$ each regardless of size. Growers normally sell the trees by the tree or by the foot. The price is the weighted average tree price (rounded down) for all species in the El Dorado and Placer region for the 2004 season based on Christmas Tree Association data. Sales tax is not collected in this study.

Miscellaneous Site Preparation. Site preparation for tree sales includes tractor time for smoothing the roads and parking areas as well as miscellaneous labor for putting up signs, marking the parking lots, sanitation facilities, other necessary preparations and miscellaneous supplies for the sale of the trees. Times and costs are estimated and not taken from any specific data.

Taxes. Besides income taxes, the Christmas tree business requires the reporting and payment of taxes, most of which are not included in this study.

Sales Tax. In this study, the returns collected are net of sales tax. The grower collects sales taxes at the local county rate at the time of sale of each Christmas tree. The amounts are reported and paid to the state by the grower. For further information see the Board of Equalization website at http://www.boe.ca.gov.

Timber Tax. The trees sold are subject to the timber tax as assessed by the California State Board of Equalization. The tax is based on lineal yield and is separate from the sales tax. The tax is not included in this study. For further information see the Board of Equalization website.

Income Tax. The income received from a Choose \& Cut Christmas Tree Farm is subject to income taxes. Timber as defined under the Internal Revenue Code includes evergreen trees that are more than six years old at the time they are cut (separated from their roots) and sold for ornamentals. Net gains from sales of Christmas trees can qualify as capital gains income rather than ordinary income, possibly resulting in lower taxes. Certain bookkeeping requirements are required to qualify for the capital gains treatment. See your accountant or tax preparer. Online information may found at http://www.timbertax.org.

Labor. A minimum amount of skilled machine labor is required on the tree farm. The laborer operates a small garden type tractor; therefore one wage is used for both machine operation and general labor. Labor rates are $\$ 10.96$ for general and machine labor and includes payroll overhead of $37 \%$. The basic hourly wages are $\$ 8.00$. The overhead includes the employers' share of federal and California state payroll taxes, workers' compensation insurance for nurseries (code 0005), and a percentage for other possible benefits. Workers' compensation insurance costs will vary among growers, but for this study the cost is based upon the average industry final rate as of January 1, 2005 (California Department of Insurance). Labor for operations involving machinery are 20\% higher than the operation time given to account for the extra labor involved in equipment set up, moving, maintenance, work breaks, and field repair.

Wages for management are not included as a cash cost. Any return above total costs is considered a return to management. However, growers wanting to account for management may wish to add a fee. The manager makes all production decisions including cultural practices, action to be taken on pest management recommendations, and labor.

Equipment Operating Costs. Repair costs are based on purchase price, annual hours of use, total hours of life, and repair coefficients formulated by American Society of Agricultural Engineers (ASAE). Fuel and lubrication costs are also determined by ASAE equations based on maximum Power Take Off (PTO) horsepower, and fuel type. Prices for on-farm delivery of diesel and gasoline are $\$ 1.51$ and $\$ 2.05$ per gallon, respectively. The price is projected based on random sampling of dealers in January 2005 and 2004 trends from various reporting agencies. The cost includes a $2 \%$ local sales tax on diesel fuel and $8 \%$ sales tax on gasoline. Gasoline also includes federal and state excise tax, which are refundable for on-farm use when filing your income tax. Tractor time is $10 \%$ higher than implement time for a given operation to account for setup, travel and down time.

Interest On Operating Capital. Interest on operating capital is based on cash operating costs and is calculated monthly until harvest at a nominal rate of $7.65 \%$ per year. A nominal interest rate is the typical market cost of borrowed funds. The interest cost of post harvest operations is discounted back to the last harvest month using a negative interest charge.

Environmental Costs. Growers are subject to various local, state, and federal environmental regulations. These costs vary considerably by location and are difficult to quantify; therefore, they are not included as a cost in this study. Some sample environmental costs are the application process for a pesticide identification number and related continuing education classes that may be required, time for applying and implementing the permit requirements. Also, irrigation costs may include an Ag discharge waiver fee. The cost of membership in a watershed coalition varies by county, but may total $\$ 100$ or more per year per farm.

Risk. Production risks should not be minimized. While this study makes every effort to model a production system based on typical, real world practices, it cannot fully represent financial, agronomic and market risks, which affect the profitability and economic viability.

## Cash Overhead Costs

Cash overhead consists of various cash expenses paid out during the year that are assigned to the whole farm and not to a particular operation. These costs include property taxes, interest on operating capital, office expense, liability and property insurance, sanitation services, equipment repairs, and management.

Property Taxes. Counties charge a base property tax rate of $1 \%$ on the assessed value of the property. In some counties special assessment districts exist and charge additional taxes on property including equipment, buildings, and improvements. For this study, county taxes are calculated as $1 \%$ of the average value of the property. Average value equals new cost plus salvage value divided by 2 on a per acre basis.

Insurance. Insurance for farm investments varies depending on the assets included and the amount of coverage. Property insurance provides coverage for property loss and is charged at $0.69 \%$ of the average value of the assets over their useful life. Liability insurance covers accidents on the farm and costs $\$ 429$ for the 20 acre farm. Customer insurance for choose and cut tree farms, is additional liability insurance to cover customer accidents that may occur while on the farm to purchase a tree. Costs will vary depending upon the coverage and for a 10 to 15 acre farm, the range may be from $\$ 500$ to $\$ 2,000$ for the farm. Rates will typically be higher where the customer cuts the tree versus the owner or his labor cutting the tree. A cost of $\$ 1,000$ per farm or $\$ 62.50$ per producing acre is used in this study.

Office Expense. Office and business expenses are estimated at $\$ 120$ per producing acre ( 16 acres). These expenses include office supplies, telephones, bookkeeping/accounting, tax preparation, legal fees, shop and office utilities, and miscellaneous administrative charges. In some counties a business license may be required for on-farm sales. The cost is a general estimate and not based on any actual data.

Marketing/Advertising. An assumed cost of $\$ 480$ per year per farm is included for organization memberships, brochures, newspaper ads and other forms of marketing to sell the trees. Marketing costs begin in the first year that trees will be sold and continue each year thereafter.

Basic Water Charge. Many water districts charge a basic monthly charge or other overhead or administrative fees. The annual farm fee in this study, based on El Dorado Irrigation District for gravity feed water is $\$ 261$ per farm or $\$ 16.27$ per producing acre ( 16 acres).

Sanitation Services. Sanitation services provide four portable toilets, washbasins, soap, and towels for one month during harvest. The cost is based on grower input.

Management/Supervisor Salaries. The grower farms the orchard; therefore no salaries are included for management. Returns above costs are considered a return to management.

Investment Repairs. Annual maintenance is calculated as two percent of the purchase price.

## Non-Cash Overhead

Non-cash overhead is calculated as the capital recovery cost for equipment and other farm investments.
Capital Recovery Costs. Capital recovery cost is the annual depreciation and interest costs for a capital investment. It is the amount of money required each year to recover the difference between the purchase price and salvage value (unrecovered capital). It is equivalent to the annual payment on a loan for the investment with the down payment equal to the discounted salvage value. This is a more complex method of calculating ownership costs than straight-line depreciation and opportunity costs, but more accurately represents the annual costs of ownership because it takes the time value of money into account (Boehlje and Eidman). The formula for the calculation of the annual capital recovery costs is ((Purchase Price - Salvage Value) x Capital Recovery Factor $)+($ Salvage Value x Interest Rate $)$.

Salvage Value. Salvage value is an estimate of the remaining value of an investment at the end of its useful life. For farm machinery (tractors and implements) the remaining value is a percentage of the new cost of the investment (Boehlje and Eidman). The percent remaining value is calculated from equations developed by the American Society of Agricultural Engineers (ASAE) based on equipment type and years of life. The life in years is estimated by dividing the wear out life, as given by ASAE by the annual hours of use in this operation. For other investments including irrigation systems, buildings, and miscellaneous equipment, the value at the end of its useful life is zero. The salvage value for land is the purchase price because land does not depreciate. The purchase price and salvage value for equipment and investments are shown in the tables.

Capital Recovery Factor. Capital recovery factor is the amortization factor or annual payment whose present value at compound interest is 1 . The amortization factor is a table value that corresponds to the interest rate used and the life of the machine.

Interest Rate. The interest rate of $7.65 \%$ used to calculate capital recovery cost is the USDA-ERSs tenyear average of California's agricultural sector long-run rate of return to production assets from current income. It is used to reflect the long-term realized rate of return to these specialized resources that are used effectively in the agricultural sector.

Irrigation System. A drip irrigation system is installed and the estimated price includes the drip lines, laterals, booster pump, and filters.

Land. Small land parcels (20 acres or less) in the region are being purchased for home sites. Afterwards, the landowner may plant an agricultural crop on a portion of the land. In this study, the two acre home site and unplantable acres are not included in the land costs. An agricultural value estimated at $\$ 12,000$ per acre from farm real estate sales in the area is established for the 18 acres.

Building. The buildings total 480 square feet and are used for shop, storage, and tree sales.
Tools. This includes shop tools, hand tools, and miscellaneous field tools such as planting and pruning tools, backpack sprayers, and saws for cutting the trees.

Balers and Tables. The grower owns three balers (netting machines) and tables for wrapping the sold trees. The equipment is purchased the first year trees are sold and is the cost is allocated to the Douglas fir the first two years and to the entire farm once the white fir trees come into production.

Equipment. Farm equipment is purchased new or used, but the study shows the current purchase price for new equipment. The new purchase price is adjusted to $60 \%$ to indicate a mix of new and used equipment. Annual ownership costs for equipment and other investments are shown in the Whole Farm Annual Equipment, Investment, and Business Overhead Costs table. Equipment costs are composed of three parts: non-cash overhead, cash overhead, and operating costs. Both of the overhead factors have been discussed in previous sections. The operating costs consist of repairs, fuel, and lubrication and are discussed under operating costs.

Table Values. Due to rounding, the totals may be slightly different from the sum of the components.
