## INTRODUCTION

The sample costs to produce raspberries in Santa Cruz and Monterey Counties are presented in this study. The study is intended as a guide only, and can be used to make production decisions, determine potential returns, prepare budgets and evaluate production loans. The practices described are based on production procedures considered typical for this crop and area, and may not apply to every farm. Sample costs for labor, materials, equipment and custom services are based on current figures. A blank column, "Your Cost", is provided to enter your actual costs on Tables 1 and 3.

The hypothetical farm operation, production practices, overhead, and calculations are described under assumptions. For additional information or explanation of calculations used in the study call the Department of Agricultural and Resource Economics, University of California, Davis, (530) 752-3589 or the UC Cooperative Extension office in your county.

Sample Cost of Production studies for many commodities from 1931 to the present are available and can be requested through the Department of Agricultural and Resource Economics, UC Davis, (530) 752-4424. Current studies may also be downloaded from the department Web site http://coststudies.ucdavis.edu or obtained from selected county UC Cooperative Extension offices.

## ASSUMPTIONS

The following assumptions refer to calculations in Tables 1 to 10 beginning on page 11 and pertain to sample costs to establish and produce raspberries in the Central Coast Region - Santa Cruz and Monterey Counties. Practices described represent methods considered typical for raspberry production in the region. The costs, practices, and materials will not be applicable to all situations every production year. Cultural practices, materials, and raspberry production costs vary by grower and region, and differences can be significant. The practices and inputs used in the cost study serve as a guide only. The use of trade names and cultural practices in this report does not constitute an endorsement or recommendation by the University of California nor is any criticism implied by omission of other similar products or cultural practices.

Farm. The farm consists of 30 contiguous acres of land. Raspberries are planted on 15 acres. Other berries are planted on 12 acres; roads, the irrigation system and farmstead account for three acres. In this area, a few operations will rotate berry crops with vegetables and other row crops. The grower rents the land for $\$ 2,000$ per acre per year, and owns the equipment and machinery.

## Establishment Cultural Practices and Material Inputs

Tables 1, 2, 10
Raspberries are a perennial crop that, when well managed, can produce for up to 20 years. However, in California, raspberries are managed as a biennial crop, the intent of which is to keep production and economic returns high. In this study we consider costs and returns associated with the establishment of a raspberry crop along with costs and returns for two production cycles. The establishment costs comprise the seven months from August in one calendar year to February of the following calendar year. That is, from land preparation to the installation of the trellis and drip irrigation systems. The production cycle is from March to October for each of the two years.

Land Preparation. Land is prepared for planting by first subsoiling in August, followed by disking three times and rototilling once. Six tons of well composted manure is applied and incorporated into the soil at the same time as the disking operations. Beds are then listed and shaped. Fertilizer is applied prior to planting. During the growing season, the grower applies additional fertilizer through the drip irrigation system as shown below.

Fertilization. To decide upon the fertilizer and rate to be applied, a soil sample is taken for soil analysis in the spring before starting land preparation. Composted manure at six tons per acre is applied during land preparation. Four hundred pounds of 15-15-15 is band applied before planting. Additional fertilizer may be applied during the growing season.

Pest Management. The pesticides and rates mentioned in this cost study as well as other materials available are listed in UC Integrated Pest Management Guidelines, Caneberries. Pesticides mentioned in the study are commonly used, but are not recommendations.

Soil Fumigation. The soil is fumigated with a combination of Telone and chloropicrin to manage pests, which can include diseases, arthropods and weed seeds. This operation is done after the ground has been subsoiled, disked and rototilled, and approximately three weeks prior to planting. A custom operator fumigates the field using a rate of 14 gallons per acre of Telone and 200 pounds per acre of chloropicrin. The cost of the application in this study is $\$ 1,650$ per acre.

Planting. Several raspberry varieties are planted in the region, however, no specific variety is assumed in this study. The price depends on the variety selected and on a possible storage charge; for this study the cost per plant is $\$ 0.48$. Planting is done by hand, and takes about 12 man-hours per acre to plant at an approximate cost of $\$ 124$ per acre. Raspberries are generally transplanted from late November through March on 10 -foot rows with a between plant spacing of 18 -inches for a total plant density of 2,900 plants per acre. Leader buds and root suckers, which grow from the crown and roots, will fill in the spaces in between plants during the growing season.

Raspberries are classified as floricane (summer bearing) and primocane (fall bearing) varieties. Floricane-bearing raspberries grow vegetatively during the first season, and bear fruit during the second season. After harvest, canes that produced fruit should be removed leaving the new canes that will produce fruit to be harvested in the following year. Because of the cost and effort of maintaining the floricane-bearing varieties vegetatively for the first season, many growers opt for primocane varieties, which produce fruit bearing canes every year starting from the fall of the first growing year. This study assumes that the grower uses primocane-bearing varieties.

Irrigation. After transplanting, a temporary overhead sprinkler irrigation system is set-up to irrigate the crop for three weeks and then removed. Overhead irrigation on established plants may increase the incidence of fruit rot and other diseases as the crop matures. During the winter, crop growth is generally dependent on seasonal rains, but later in the season a drip irrigation system is installed and used to irrigate the crop. The drip line is tied to the lower wire of the trellis with emitters placed every 18 -inches. The drip line is discarded after the second harvest, when the trellis is removed.

Trellising. Based on a square acre basis ( $200 \mathrm{ft} \times 218 \mathrm{ft}$ ), the berries will have 20 rows per acre. The trellis system consists of at least four wires; two located 20 -inches from the ground, and another two at 54 -inches from the ground. Two-inch posts separated 15 feet and four-inch end posts that anchor them, support the wires. Per row cost of materials is as follows: fourteen two-inch by eight-foot pressure treated posts at $\$ 6.25$ each; two four-inch by seven-foot pressure treated end posts at $\$ 7.25$ each; 16 gauge trellising wire at $\$ 7.91$ per 1,000 feet; four line post clips at $\$ 0.06$ per post. The total cost (materials plus labor) of installing the trellis was estimated at $\$ 2,200$ per acre. Because trellis materials can be used for six years, this cost is included in non-cash or investment overhead. However, labor cost is considered part of the establishment cost. Total labor was estimated at 41 hours per acre.

Shade. A shade structure is set up in the spring to provide shade for the labor and for a sorting and packing area at harvest. The costs include the setup labor and miscellaneous expenses for materials. The shade structure may also be used for future crops.

## Production Cultural Practices and Material Inputs

Tables 3-10
Irrigation. Depending on effective rainfall and available soil moisture, plants are irrigated from March through September using between one-half and one-inch of water per week during the growing season. Total irrigation water during the season is approximately two acre-feet. The cost of water includes pumping costs of $\$ 90$ per acre foot or $\$ 7.50$ per acre inch plus labor. Growers producing within the Pajaro Valley Water Management Agency (PVWMA) district are charged an additional $\$ 160$ per acre foot or $\$ 13.33$ per acre inch augmentation fee for all pumped (well-drawn) water.

Fertilization. In season fertilizers are applied through the drip system. Leaf analysis is done around mid-season (May) to determine the nutritional needs of the plants. It is recommended that plants receive liquid fertilizer via the irrigation system through the growing season roughly every 14 days. A common liquid fertilizer is 15-10-30, although a variety of formulations are commercially available.

Pest Management. The pesticides and rates mentioned in this cost study are listed in UC Integrated Pest Management Guidelines, Caneberries. For information on other pesticides available, pest identification, monitoring, and management visit the UC IPM website at www.ipm.ucdavis.edu or contact your local UCCE farm advisor. Information and pesticide use permits are available through the local county agricultural commissioner's office. Pesticides mentioned in this study are used to calculate rates and costs. Although growers commonly use the pesticides mentioned, other pesticides are available. Spray adjuvants are recommended for use with many pesticides, but are not accounted for in this study. Pesticide costs vary by location, brand, and grower volume. Pesticide costs in this study are from a single dealer and shown as full retail.

Pest Control Adviser (PCA). The PCA monitors the field for agronomic problems including pests, diseases, and nutritional status. Growers may hire private consultants on a per acre basis or receive the service as part of an agreement with an agricultural chemical and fertilizer company. Costs of $\$ 100$ per acre for a private PCA are included in this study.

Diseases. Fungicides are applied in the spring to control diseases such as yellow rust (copper sulfate, 5 pounds per acre) and Botrytis (Elevate, 1.5 pounds per acre) In this study, Elevate is applied three times - twice in April and once in June; Copper (Kocide) is applied twice in May.

Insects (Arthropods). Savey is applied for the control of two-spotted spider mite, once in April at 6 ounces per acre.

Weeds. For this study, weed control is done by hand (hoeing) in May and June, and is assumed to take nine man-hours per month. Alternately, a grower may chose to use a disk harrow during spring and summer. The use of a disk harrow to cultivate weeds between rows is a delicate operation because of the risk posed to injuring the raspberries' shallow root system. Spacing within rows is important so that vegetative growth covers the ground to help shade out weeds.

Pollination. Bees are needed for pollination, at a rate of two hives per acre. Bee hives are set up by a contractor in the winter and removed by the end of that season. The cost is $\$ 30$ per hive.

Harvest. Harvest season starts in August and extends through October, and may be longer if the crop is grown using protective tunnels. Raspberries are harvested by hand every few days at an average seasonal piece rate cost of $\$ 4.00$ per flat. Early season (lower yields), the piece rate cost is usually higher. Crew size and number of crews may vary through the season depending upon the yield. Picking rate per picker ranges from one to three flats per hour, with the lesser rate occurring early and late in the season. For this study, it assumed that an average picking rate for the season is 2.5 flats per hour. The fruit is picked using one gallon buckets; then field sorted and packed into a flat containing 12 one-half pint plastic clam shells. Each full flat weighs 7 pounds. The area under the shade structure, constructed during the establishment period, is used for packing and sorting. Harvesting consist of one crew of 25 that hand picks the berries, a crew supervisor and a checker-loader who records the flats picked by each crewmember and who also loads the flats on the pallets on the truck. The truck holds up to two pallets with 144 flats and takes one hour round trip to deliver the fruit to the cooler. To prevent the fruit from heating up, the truck should make deliveries to the cooler with less than full loads. The fruit is then transported by the grower to a cooler, where the grower pays $\$ 0.85$ per flat for cooling services.

Yields and Returns. This study assumes an average marketable yield of 3,000 seven-pound flats per acre, which is equivalent to approximately 10 tons per acre. The expected unit price is $\$ 12$ per flat based on Santa Cruz County Agricultural Commissioner's Crop Reports and the USDA Agricultural Marketing Service shipping point prices from Salinas/Watsonville area. Estimated returns for a range of yields and prices are shown in Table 6.

Post harvest pruning/clean up. After the first harvest, the dead canes or those that have fruited are pruned out by hand, at 30 hours per acre. Part of the pruning operation will include adjustment of the primocanes in the trellis for the following year if the field is left in place. Canes left on the ground are then disked shallowly and incorporated into the soil. By the end of the second year the crop is completely removed, as well as the drip tape and the trellis system. The trellis may be reusable, but the drip tape is discarded. Trellis and drip tape removal are done by hand. The canes are disked to prepare the land for a subsequent crop: raspberries, another berry crop, or a vegetable crop depending on a grower's rotation scheme. The postharvest clean up operation takes approximately 18 hours per acre to be completed. For simplicity purposes the cost of pruning after the first harvest ( 30 hours) and the cost of the final clean up operation ( 18 hours) are averaged over the two production years.

## Labor, Equipment, and Interest Costs

Pickup/ATV. It is assumed that the pickup is used for business and personal use. The grower uses the ATV for collecting the soil and leaf samples and is included in those costs. The ATV is also used to check the field, monitor the irrigation, and other miscellaneous use. The time and mileage use for the pickup and ATV operations are estimated and not taken from any specific data.

Labor. The basic hourly wage for equipment operators is $\$ 11.50$ per hour and for general labor is $\$ 7.50$ per hour. At harvest, the pickers receive piece rate pay of $\$ 4.00$ per flat. This is an average seasonal piece rate cost. At the beginning of the season due to lower yields, the piece rate is higher ( $\$ 4.50$ to $\$ 5.00$ ) than during the peak season. Adding payroll overhead of $38 \%$ to the hourly wage gives labor rates of $\$ 15.87$ for equipment operators and $\$ 10.35$ per hour for general labor. The overhead includes the employers' share of federal and California state payroll taxes, workers' compensation insurance for truck crops (code 0172), and a percentage for other possible benefits. Workers' compensation insurance costs will vary among growers, but for this study the cost is based upon the average industry final rate as of January 1, 2005 (California Department of Insurance). Labor for operations involving machinery are $20 \%$ higher than the operation time given in Table 3 to account for the extra labor involved in equipment set up, moving, maintenance, work breaks, and field repair.

Equipment Operating Costs. Repair costs are based on purchase price, annual hours of use, total hours of life, and repair coefficients formulated by American Society of Agricultural Engineers (ASAE). Fuel and lubrication costs are also determined by ASAE equations based on maximum power takeoff (PTO) horsepower, and fuel type. Prices for on-farm delivery of diesel and gasoline are $\$ 2.00$ and $\$ 2.25$ per gallon, respectively. The price is based on the growers May, 2005 delivery invoice. The cost may include a $2 \%$ local sales tax on diesel fuel and $8 \%$ sales tax on gasoline. Gasoline also includes federal and state excise tax, which are refundable for on-farm use when filing your income tax. The fuel, lube, and repair cost per acre for each operation in Table 3 is determined by multiplying the total hourly operating cost in Table 8 for each piece of equipment used for the selected operation by the hours per acre. Tractor time is $10 \%$ higher than implement time for a given operation to account for setup, travel and down time.

Interest On Operating Capital. Interest on operating capital is based on cash operating costs and is calculated monthly until harvest at a nominal rate of $7.65 \%$ per year. A nominal interest rate is the typical market cost of borrowed funds. The interest cost of post harvest operations is discounted back to the last harvest month using a negative interest charge.

Risk. The risks associated with producing and marketing raspberries are considered high. While this study makes every effort to model a production system based on typical, real world practices, it cannot fully represent financial, agronomic and market risks that affect the profitability and economic viability.

## Cash Overhead

Cash overhead consists of various cash expenses paid out during the year that are assigned to the whole farm and not to a particular operation. These costs include property taxes, interest on operating capital, office expense, liability and property insurance, sanitation services, equipment repairs, and management.

Property Taxes. Counties charge a base property tax rate of $1 \%$ on the assessed value of the property. In some counties special assessment districts exist and charge additional taxes on property including equipment, buildings, and improvements. For this study, county taxes are calculated as $1 \%$ of the average value of the property. Average value equals new cost plus salvage value divided by 2 on a per acre basis.

Insurance. Insurance for farm investments vary depending on the assets included and the amount of coverage. Property insurance provides coverage for property loss and is charged at $0.690 \%$ of the average value of the assets over their useful life. Liability insurance covers accidents on the farm and costs $\$ 529$ for the entire farm.

Office Expense. Office and business expenses are estimated at $\$ 300$ per producing acre. These expenses include office supplies, telephones, bookkeeping, accounting, legal fees, road maintenance, utilities, and miscellaneous expenses.

Land Rent. The grower pays $\$ 2,000$ per acre per year for the 30 -acres or $\$ 2,222$ per acre per producing acre (27 acres).

Sanitation Services. Sanitation services provide a double portable toilet and single toilet with washing equipment and cost the farm $\$ 3,080$ annually.

Food Safety Program. Many growers of fresh market commodities such as raspberries now incorporate and participate in food safety programs for their operations. Part of a food safety program is participation in third party (independent) audits, that are done to accommodate buyer requests and to enhance marketability of the crop. Costs will vary depending upon farm or inspection circumstances. For this study, costs for the farm are estimated at $\$ 750$ per year.

## Non-Cash Overhead

Non-cash overhead, shown on an annual per acre basis, is calculated as the capital recovery cost for equipment and other farm investments.

Capital Recovery Costs. Capital recovery cost is the annual depreciation and interest costs for a capital investment. It is the amount of money required each year to recover the difference between the purchase price and salvage value (unrecovered capital). It is equivalent to the annual payment on a loan for the investment with the down payment equal to the discounted salvage value. This is a more complex method of calculating
ownership costs than straight-line depreciation and opportunity costs, but more accurately represents the annual costs of ownership because it takes the time value of money into account (Boehlje and Eidman). The formula for the calculation of the annual capital recovery costs is ((Purchase Price - Salvage Value) x Capital Recovery Factor $)+($ Salvage Value x Interest Rate $)$.

Salvage Value. Salvage value is an estimate of the remaining value of an investment at the end of its useful life. For farm machinery (tractors and implements) the remaining value is a percentage of the new cost of the investment (Boehlje and Eidman). The percent remaining value is calculated from equations developed by the American Society of Agricultural Engineers (ASAE) based on equipment type and years of life. The life in years is estimated by dividing the wear out life, as given by ASAE by the annual hours of use in this operation. For other investments including irrigation systems, buildings, and miscellaneous equipment, the value at the end of its useful life is zero. The salvage value for land is the purchase price because land does not depreciate. The purchase price and salvage value for equipment and investments are shown in Table 7.

Capital Recovery Factor. Capital recovery factor is the amortization factor or annual payment whose present value at compound interest is 1 . The amortization factor is a table value that corresponds to the interest rate used and the life of the machine.

Interest Rate. The interest rate of $6.01 \%$ used to calculate capital recovery cost is the USDA-ERSs ten-year average of California's agricultural sector long-run rate of return to production assets from current income. It is used to reflect the long-term realized rate of return to these specialized resources used effectively in the agricultural sector.

Buildings. The 1,400 square feet of metal buildings may be a shop, overheads, shade structures or storage.
Trellis. The trellis is installed in the establishment year soon after planting. The trellis system has a life of six years and is removed at the end of the growing season and used on other plantings. The cost includes the materials whereas the labor is charged to the years affected by the installation and removal.

Shop/Field Tools. Shop, hand, and various small field tools are included in these costs. Tools vary considerably from farm to farm and the cost does not represent any specific inventory.

Irrigation Pump \& Well. This study assumes that the grower refurbished the 40 HP electric pump and well that services the farm. In general, growers in the region are responsible for the portion above the ground such as the pump, and the landowner is responsible for what is below ground such as the well running dry.

Irrigation System. The irrigation system includes the filtration system and laterals that connect to the drip line.
Water is pumped through the filtration station into the main lines. Reusable telescoping lateral lines are buried at the edge of the raspberry field and are connected to the main and drip lines. The drip lines are included in the establishment costs because they will be replaced at the end of the two year period when the berry canes are removed.

Sprinkler Pipe. The sprinkler system is an estimated cost by a local dealer for enough sprinkler pipe, sprinklers and main line to make five acre sets. The pipe is hand movable and may be used on all farm crops.

Establishment Cost. Costs to establish the berry canes are used to determine capital recovery expenses, depreciation, and interest on investment for the production years. Establishment cost is the sum of the costs for land preparation, trellis system labor, drip tape, planting, plants, cash overhead and expenses for establishing the
canes. The costs cover a seven month period from August to February. The Total Cash Cost on Table 1 represents the establishment cost. For this study the cost is $\$ 5,868$ per acre or $\$ 88,028$ for the 15 -acre field. The establishment cost is spread over the two crop production years.

Equipment Costs. Farm equipment is purchased new or used, but the study shows the current purchase price for new equipment. The new purchase price is adjusted to $60 \%$ to indicate a mix of new and used equipment. Annual ownership costs for equipment and other investments are in the Whole Farm Equipment, Investment and Business Overhead Tables. Equipment costs are composed of three parts: non-cash overhead, cash overhead, and operating costs. Both of the overhead factors have been discussed in previous sections. The operating costs consist of repairs, fuel, and lubrication and are discussed under operating costs.

Table Values. Due to rounding, the totals may be slightly different from the sum of the components.
